

Turnout against Saïed's share — delegation level

Pearson $r = +0.185$ across 259 delegations; the fitted line rises $+0.19$ points of Saïed's share per point of turnout. Points are sized by registered electorate, so the large circles carry the votes.

The relationship most often assumed about this election is not in this data. Across the 8,403 stations on the same basis r is $+0.058$, against $+0.185$ here — both near zero, and the difference between them is a modifiable areal unit effect rather than a finding: the same votes, aggregated two ways.

Units below 50% turnout coverage are excluded here as on the maps.

The registered count is the only field in this dataset that no identity on the form checks — the one field read by classifier alone — so turnout is a certified numerator over an uncertified denominator, and is weaker evidence than any candidate figure mapped elsewhere in this directory.
