

Ayachi Zammel — spatial clusters

local Moran's I, delegation level · Benjamini-Hochberg $q = 0.05$

- LISA class
- high in a high neighbourhood — HH (9)
 - low in a low neighbourhood — LL (0)
 - high in a low neighbourhood — HL (0)
 - not significant (255)

264 mapped units

global Moran's I = +0.552 ($p < 0.0001$, 9,999 permutations, pseudo $z = +14.2$). The map localises that: a class is assigned only where the unit's own neighbourhood is more extreme than 9,999 random neighbourhoods drawn from the same values, after Benjamini-Hochberg correction across all 264 units (threshold actually applied: $p \leq 0.0014$). Uncorrected, 48 units reach $p \leq 0.05$ — which is what an uncorrected LISA map would shade, and at 264 tests about 13 of those are expected by chance alone. Empirical-Bayes standardising the rate, so a small unit's noisy share is not read as geography, reclassifies 1 unit(s).
