

Zouhair Maghzaoui — spatial clusters

local Moran's I, delegation level · Benjamini-Hochberg q = 0.05

- LISA class
- high in a high neighbourhood — HH (5)
 - low in a low neighbourhood — LL (0)
 - high in a low neighbourhood — HL (0)
 - not significant (258)
 - low in a high neighbourhood — LH (1)

264 mapped units

global Moran's I = +0.375 (p < 0.0001, 9,999 permutations, pseudo z = +11.0). The map localises that: a class is assigned only where the unit's own neighbourhood is more extreme than 9,999 random neighbourhoods drawn from the same values, after Benjamini-Hochberg correction across all 264 units (threshold actually applied: $p \leq 0.0009$). Uncorrected, 55 units reach $p \leq 0.05$ — which is what an uncorrected LISA map would shade, and at 264 tests about 13 of those are expected by chance alone. Empirical-Bayes standardising the rate, so a small unit's noisy share is not read as geography, reclassifies 0 unit(s).
